CS 114 Spring 2019

Slides from Roger Grosse

Overview

• Recall the simple neuron-like unit:

 These units are much more powerful if we connect many of them into a neural network.

Overview

Design choices so far

- Task: regression, binary classification, multiway classification
- Model/Architecture: linear, log-linear, feed-forward neural network
- Loss function: squared error, 0-1 loss, cross-entropy, hinge loss
- Optimization algorithm: direct solution, gradient descent, perceptron

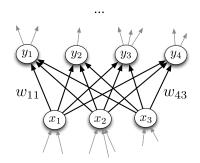

- We can connect lots of units together into a directed acyclic graph.
- This gives a feed-forward neural network. That's in contrast to recurrent neural networks, which can have cycles. (We'll talk about those later.)
- Typically, units are grouped together into layers.

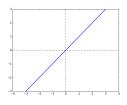

- Each layer connects *N* input units to *M* output units.
- In the simplest case, all input units are connected to all output units. We call this
 a fully connected layer. We'll consider other layer types later.
- Note: the inputs and outputs for a layer are distinct from the inputs and outputs to the network.
- Recall from multiway logistic regression: this means we need an $M \times N$ weight matrix.
- The output units are a function of the input units.

$$\mathbf{y} = f(\mathbf{x}) = \phi(\mathbf{W}\mathbf{x} + \mathbf{b})$$

 A multilayer network consisting of fully connected layers is called a multilayer perceptron. Despite the name, it has nothing to do with perceptrons!

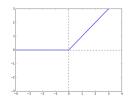

Some activation functions:

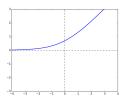

Linear

$$y = z$$

Rectified Linear Unit (ReLU)

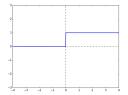

$$y = \max(0, z)$$

Soft ReLU

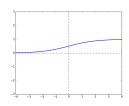

$$y = \log 1 + e^z$$

Some activation functions:

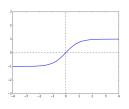

Hard Threshold

$$y = \left\{ \begin{array}{ll} 1 & \text{if } z > 0 \\ 0 & \text{if } z \le 0 \end{array} \right.$$

Logistic

$$y = \frac{1}{1 + e^{-z}}$$

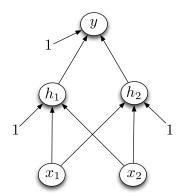

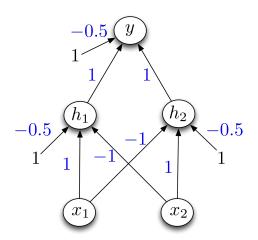

Hyperbolic Tangent (tanh)

$$y = \frac{e^z - e^{-z}}{e^z + e^{-z}}$$

Designing a network to compute XOR:

Assume hard threshold activation function

 Each layer computes a function, so the network computes a composition of functions:

$$\mathbf{h}^{(1)} = f^{(1)}(\mathbf{x})$$
 $\mathbf{h}^{(2)} = f^{(2)}(\mathbf{h}^{(1)})$
 \vdots
 $\mathbf{y} = f^{(L)}(\mathbf{h}^{(L-1)})$

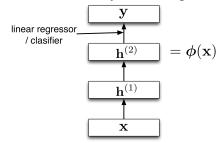

Or more simply:

$$\mathbf{y}=f^{(L)}\circ\cdots\circ f^{(1)}(\mathbf{x}).$$

 Neural nets provide modularity: we can implement each layer's computations as a black box.

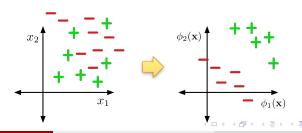

• Neural nets can be viewed as a way of learning features:

• Neural nets can be viewed as a way of learning features:

• The goal:

Input representation of a digit: 784 dimensional vector.

```

Each first-layer hidden unit computes $\sigma(\mathbf{w}_i^T \mathbf{x})$

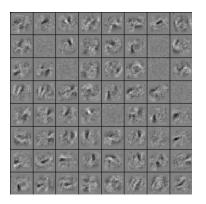

Here is one of the weight vectors (also called a feature).

It's reshaped into an image, with gray = 0, white = +, black = -.

To compute $\mathbf{w}_{i}^{T}\mathbf{x}$, multiply the corresponding pixels, and sum the result.

There are 256 first-level features total. Here are some of them.

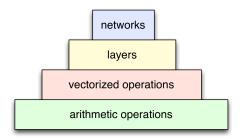

Levels of Abstraction

The psychological profiling [of a programmer] is mostly the ability to shift levels of abstraction, from low level to high level. To see something in the small and to see something in the large.

- Don Knuth

Levels of Abstraction

When you design neural networks and machine learning algorithms, you'll need to think at multiple levels of abstraction.

- We've seen that there are some functions that linear classifiers can't represent. Are deep networks any better?
- Any sequence of *linear* layers can be equivalently represented with a single linear layer.

$$\mathbf{y} = \underbrace{\mathbf{W}^{(3)}\mathbf{W}^{(2)}\mathbf{W}^{(1)}}_{\triangleq \mathbf{W}'}\mathbf{x}$$

- Deep linear networks are no more expressive than linear regression!
- Linear layers do have their uses stay tuned!

- Multilayer feed-forward neural nets with nonlinear activation functions are universal approximators: they can approximate any function arbitrarily well.
- This has been shown for various activation functions (thresholds, logistic, ReLU, etc.)
 - Even though ReLU is "almost" linear, it's nonlinear enough!

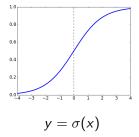

Universality for binary inputs and targets:

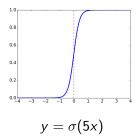

- Hard threshold hidden units, linear output
- Strategy: 2^D hidden units, each of which responds to one particular input configuration

x_1	x_2	x_3	t	
	:		:	/ 1
-1	-1	1	-1	
-1	1	-1	1	2.5
-1	1	1	1	
	:		:	-1 1 -1
			1 -	

• Only requires one hidden layer, though it needs to be extremely wide!

- What about the logistic activation function?
- You can approximate a hard threshold by scaling up the weights and biases:

• This is good: logistic units are differentiable, so we can tune them with gradient descent. (Stay tuned!)

- Limits of universality
 - You may need to represent an exponentially large network.
 - If you can learn any function, you'll just overfit.
 - Really, we desire a compact representation!

- Limits of universality
 - You may need to represent an exponentially large network.
 - If you can learn any function, you'll just overfit.
 - Really, we desire a compact representation!
- We've derived units which compute the functions AND, OR, and NOT. Therefore, any Boolean circuit can be translated into a feed-forward neural net.
 - This suggests you might be able to learn compact representations of some complicated functions
 - The view of neural nets as "differentiable computers" is starting to take hold. More about this when we talk about recurrent neural nets.
